Download Serial Monitor Ever since the Facebook Hack Attack, users have been more wary of what they put on their social profiles. For many, the rise of this hack was a clear signal that a lot of online activity is stored elsewhere than just where one expects it to be: on the individual's PC. Now, this has given rise to a new type of data hiding—one that's rather simple and more effective than many other, more elaborate methods. In fact, the portion of the href referring to the website's actual address is in fact not editable. This has a double effect on the user, preventing them from simply searching for what they're looking for and thus, keeping them on the website's domain. Now, with Internet Info Hiding (I.I.H.), users can replace the valid address with another string, which means they can bypass the censorship and see the actual address. It's a very simple process and is easier to execute than most other methods of data hiding. The procedure is simple enough that it's easy to overlook. With the simple process of editing the Element's Href attribute, users can make do with simple trickery and update the href to their advantage. To begin, users just need to Google for the version of the browser they're using, its current user agent string and
